

# Boolean chains \*

Alberto Paoluzzi

February 28, 2015

## Abstract

A novel algorithm for computation of Boolean operations between cellular complexes is given in this module. It is based on bucketing of possibly interacting geometry using a box-extension of kd-trees, normally used for point proximity queries. Such kd-tree representation of containment boxes of cells, allow us to compute a number of independent buckets of data to be used for local intersection, followed by elimination of duplicated data. Actually we reduce the intersection of boundaries in 3D to the independent intersections of the buckets of (transformed) faces with the 2D subspace  $z = 0$ , in order to reconstruct each splitted facet of boolean arguments, suitably transformed ther together with the bucket of indent facets. A final tagging of cells as either belonging or not to each operand follows, allowing for fast extraction of Boolean results between any pair of chains (subsets of cells). This Boolean algorithm can be considered of a *Map-Reduce* kind, and hence suitable of a distributed implementation over big datasets. The actual engineered implementation will follow the present prototype, using some distributed NoSQL database, like MongoDB or Riak.

## 1 Introduction

## 2 Preview of the algorithm

The whole Boolean algorithm is composed by four stages in sequence, denoted in the following as *Unification*, *Bucketing*, *Intersection*, and *Reconstruction*. The algorithm described here is both multidimensional and variadic. Multidimensional means that the arguments are solid in Euclidean space of dimension  $d$ , with  $d$  small integer. The *arity* of a function or operation is the number of arguments or operands the function or operation accepts. In computer science, a function accepting a variable number of arguments is called *variadic*.

### 2.1 Unification

In this first step the boundaries of the  $n$  Boolean arguments are computed and merged together as a set of chains defined in the discrete set  $\mathbf{V}$  made by the union of their vertices, and possibly by a discrete set of points generated by intersection of cells of complementary dimension, i.e. whose dimensions add up to the dimension of the ambient space. Actually, only the (*oriented*) boundaries  $\mathbf{V}, \mathbf{FV}_i$  ( $1 \leq i \leq n$ ) of the various arguments are retained here, and used by the following steps of the algorithm.

### 2.2 Bucketing

The bounding boxes of facets  $\mathbf{FV}_i$  are computed, and their *box-kd-tree* is worked-out, so providing a group of buckets of close cells, that can be elaborated independently, and possibly in parallel, to compute the intersections of the boundary cells.

## 2.3 Intersection

For each facet  $f$  of one of Boolean arguments, the subset  $F(f)$  of incident or intersecting facets of boundaries of the other arguments were computed in the previous *bucketing* step. So, each  $F$  is transformed by the affine map that sends  $f$  into the  $z = 0$  subspace, and there is intersected with this subspace, generating a subset  $E(f)$  of coplanar edges. This one is projected in 2D, and the *regularized* cellular 2-complex  $G(f)$  induced by it is computed, and mapped back to the original space position and orientation of  $f$  (providing a partition of it induced by the other boundaries).

## 2.4 Reconstruction

Like for in the reconstruction of 2D solid cells using the angular ordering of edges around the vertices, the coincident edges are identified in 3D, and used to sort the incident faces using the values of solid angles given with one reference face. The 3D space partition induced by  $\cup_f G(f)$  is finally reconstructed, possibly in parallel, by traversing the adjacent sets of facets on the boundary of each solid cell.

# 3 Implementation

## 3.1 Box-kd-tree

**Split the boxes between the (below,above) subsets**

```

## 3.2 Merging the boundaries

### 3.3 Elementary splitting

In this section we implement the splitting of  $(d-1)$ -faces, stored in **FV**, induced by the buckets of  $(d-1)$ -faces, stored in **parts**, and one-to-one associated to them. Of course, (a) both such arrays have the same number of elements, and (b) whereas **FV** contains the

indices of incident vertices for each face, `parts` contains the indices of adjacent faces for each face, with the further constraint that  $i \notin \text{parts}(i)$ .

**Computation of topological relations** The function `crossRelation` is used here to compute a topological relation starting from two characteristic matrices `XV` and `YV`, that associate the sets of topological objects  $X$  and  $Y$  with their vertices, respectively. The technique using sparse binary matrices stored in CSR (Compressed Sparse Row) format is used.

⟨ Computation of topological relation 5b ⟩  $\equiv$

```
""" Computation of topological relation """
def crossRelation(XV,YV):
    csrXV = csrCreate(XV)
    csrYV = csrCreate(YV)
    csrXY = matrixProduct(csrXV, csrYV.T)
    XY = [None for k in range(len(XV))]
    for k,face in enumerate(XV):
        data = csrXY[k].data
        col = csrXY[k].indices
        XY[k] = [col[h] for h,val in enumerate(data) if val==2]
        # NOTE: val depends on the relation under consideration ...
    return XY
```

◇

Macro referenced in 8.

**Submanifold mapping computation** The  $4 \times 4$  (affine) scipy matrix `transform` of type `mat` is computed by the function `submanifoldMapping`, using as input the array `pivotFace` that contains the vertices of the so-called *pivot* face, i.e. of the face to be mapped to the coordinate subspace  $z = 0$  (in 3D).

⟨ Submanifold mapping computation 6a ⟩  $\equiv$

```
""" Submanifold mapping computation """
def submanifoldMapping(pivotFace):
    tx,ty,tz = pivotFace[0]
    transl = mat([[1,0,0,-tx],[0,1,0,-ty],[0,0,1,-tz],[0,0,0,1]])
    facet = [ VECTDIFF([v,pivotFace[0]]) for v in pivotFace ]
    m = faceTransformations(facet)
    mapping = mat([[m[0,0],m[0,1],m[0,2],0],[m[1,0],m[1,1],m[1,2],0],[m[2,0],
        m[2,1],m[2,2],0],[0,0,0,1]])
    transform = mapping * transl
    return transform
```

◇

Macro referenced in 8.

**Set of line segments partitioning a facet** The more important function of this section is the higher level `intersection` function, that accepts as input the LAR model  $(V, FV, EV)$  to be partitioned, and the pair  $(k, \text{bundledFaces})$ , where  $k$  is the index of the pivot face (to be transformed to the  $z = 0$  subspace) and where `bundledFaces` is an array of indices of faces that are guarantee to share points with face  $k$ . Such shared points may be either boundary edges of  $k$  or a segment that is internal both to face  $k$  and to some face in `bundledFaces`.

$\langle \text{Set of line segments partitioning a facet 6b} \rangle \equiv$

```

""" Set of line segments partitioning a facet """
def intersection(V,FV,EV):
    def intersection0(k,bundledFaces):
        FE = crossRelation(FV,EV)
        pivotFace = [V[v] for v in FV[k]]
        transform = submanifoldMapping(pivotFace) # submanifold transformation
        transformedCells,edges,faces = [],[],[]
        for face in bundledFaces:
            edge = set(FE[k]).intersection(FE[face]) # common edge index
            if edge == set():
                candidateEdges = FE[face]
                facet = []
                for e in candidateEdges:
                    cell = [V[v]+[1.0] for v in EV[e]] # verts of incident face
                    transformedCell = (transform * (mat(cell).T)).T.tolist()
                    # vertices in local frame
                    facet += [[point[:-1] for point in transformedCell]]
                faces += [facet]
            else: # boundary edges of face k
                e, = edge
                vs = [V[v]+[1.0] for v in EV[e]]
                ws = (transform * (mat(vs).T)).T.tolist()
                edges += [[p[:-1] for p in ws]]
        return edges,faces,transform
    return intersection0

```

Macro referenced in 8.

**Computation of face transformations** The faces in every `parts(i)` must be affinely transformed into the subspace  $x_d = 0$ , in order to compute the intersection of its elements with this subspace, that are submanifolds of dimension  $d - 2$ .

$\langle \text{Computation of face transformations 7a} \rangle \equiv$

```

""" Computation of affine face transformations """
def COVECTOR(points):

```

```

pointdim = len(points[0])
plane = Planef.bestFittingPlane(pointdim,
                                [item for sublist in points for item in sublist])
return [plane.get(I) for I in range(0,pointdim+1)]

def faceTransformations(facet):
    covector = COVECTOR(facet)
    translVector = facet[0]
    # translation
    newFacet = [ VECTDIFF([v,translVector]) for v in facet ]
    # linear transformation: boundaryFacet -> standard (d-1)-simplex
    d = len(facet[0])
    transformMat = mat( newFacet[1:d] + [covector[1:]] ).T.I
    # transformation in the subspace x_d = 0
    out = (transformMat * (mat(newFacet).T)).T.tolist()
    return transformMat

```

◇

Macro referenced in 8.

**Space partitioning via submanifold mapping** the function `spacePartition` given in the below script takes as input a *non-valid* (with the meaning used in solid modeling field — see [Req80]) LAR model of dimension  $d - 1$ , i.e. a triple  $(V, FV, EV)$ , and an array `parts` indexed on faces, and containing the subset of faces with greatest probability of intersecting each indexing face, respectively. The `spacePartition` function returns the *valid* LAR boundary model  $(W, FW, EW)$  of the space partition induced by `FV`.

⟨Space partitioning via submanifold mapping 7b⟩ ≡

```

""" Space partitioning via submanifold mapping """
def spacePartition(V,FV,EV, parts):
    transfFaces = []
    for k,bundledFaces in enumerate(parts):
        edges,faces,transform = intersection(V,FV,EV)(k,bundledFaces)
        for face in faces:
            line = []
            for edge in face:
                (x1,y1,z1),(x2,y2,z2) = edge
                if not verySmall(z2-z1):
                    x = (x2-x1)/(z2-z1) + x1
                    y = (y2-y1)/(z2-z1) + y1
                    p = [x,y,0]
                    line += [eval(vcode(p))]
            if line!=[]: edges += [line]
    print "k,edges =",k,edges
    v,fv,ev = larFromLines([[point[:-1] for point in edge] for edge in edges])
    if len(fv)>1: fv = fv[:-1]

```

```

        lar = [w+[0.0] for w in v],fv,ev

## A Code utilities

**Coding utilities** Some utility fuctions used by the module are collected in this appendix. Their macro names can be seen in the below script.

```

⟨ Coding utilities 13a ⟩ ≡
    """ Coding utilities """
    ⟨ Generation of a random 3D point 14b ⟩
    ⟨ Generation of random 3D triangles 13b ⟩
    ⟨ Generation of random 3D quadrilaterals 14a ⟩
    ⟨ Generation of a single random triangle 14c ⟩
    ⟨ Containment boxes 15a ⟩
    ⟨ Transformation of a 3D box into an hexahedron 15b ⟩
    ⟨ Computation of the 1D centroid of a list of 3D boxes 16 ⟩
    ◇

```

Macro referenced in 8.

**Generation of random triangles** The function `randomTriangles` returns the array `randomTriaArray` with a given number of triangles generated within the unit 3D interval. The `scaling` parameter is used to scale every such triangle, generated by three random points, that could be possibly located to far from each other, even at the distance of the diagonal of the unit cube.

The arrays `xs`, `ys` and `zs`, that contain the  $x, y, z$  coordinates of triangle points, are used to compute the minimal translation  $v$  needed to transport the entire set of data within the positive octant of the 3D space.

```

⟨ Generation of random 3D triangles 13b ⟩ ≡
    """ Generation of random triangles """
    def randomTriangles(numberOfTriangles=400,scaling=0.3):
        randomTriaArray = [rtriangle(scaling) for k in range(numberOfTriangles)]
        [xs,ys,zs] = TRANS(CAT(randomTriaArray))
        xmin, ymin, zmin = min(xs), min(ys), min(zs)
        v = array([-xmin,-ymin, -zmin])
        randomTriaArray = [[list(v1+v), list(v2+v), list(v3+v)] for v1,v2,v3 in randomTriaArray]
        return randomTriaArray
    ◇

```

Macro referenced in 13a.

## Generation of random 3D quadrilaterals

```

⟨ Generation of random 3D quadrilaterals 14a ⟩ ≡
    """ Generation of random 3D quadrilaterals """
    def randomQuads(numberOfQuads=400,scaling=0.3):
        randomTriaArray = [rtriangle(scaling) for k in range(numberOfQuads)]
        [xs,ys,zs] = TRANS(CAT(randomTriaArray))
        xmin, ymin, zmin = min(xs), min(ys), min(zs)
        v = array([-xmin,-ymin, -zmin])
        randomQuadArray = [AA(list)([ v1+v, v2+v, v3+v, v+v2-v1+v3 ])] for v1,v2,v3 in randomTriaArray
        return randomQuadArray
    ◇

```

Macro referenced in 13a.

**Generation of a random 3D point** A single random point, codified in floating point format, and with a fixed (quite small) number of digits, is returned by the `rpoint()` function, with no input parameters.

```

⟨ Generation of a random 3D point 14b ⟩ ≡
    """ Generation of a random 3D point """
    def rpoint():
        return eval( vcode([ random.random(), random.random(), random.random() ]) )
    ◇

```

Macro referenced in [13a](#).

**Generation of a single random triangle** A single random triangle, scaled about its centroid by the `scaling` parameter, is returned by the `rtriangle()` function, as a tuple of two random points in the unit square.

```

⟨ Generation of a single random triangle 14c ⟩ ≡
    """ Generation of a single random triangle """
    def rtriangle(scaling):
        v1,v2,v3 = array(rpoint()), array(rpoint()), array(rpoint())
        c = (v1+v2+v3)/3
        pos = rpoint()
        v1 = (v1-c)*scaling + pos
        v2 = (v2-c)*scaling + pos
        v3 = (v3-c)*scaling + pos
        return tuple(eval(vcode(v1))), tuple(eval(vcode(v2))), tuple(eval(vcode(v3)))
    ◇

```

Macro referenced in [13a](#).

**Containment boxes** Given as input a list `randomTriaArray` of pairs of 2D points, the function `containmentBoxes` returns, in the same order, the list of *containment boxes* of the input lines. A *containment box* of a geometric object of dimension  $d$  is defined as the minimal  $d$ -cuboid, equioriented with the reference frame, that contains the object. For a 2D line it is given by the tuple  $(x1,y1,x2,y2)$ , where  $(x1,y1)$  is the point of minimal coordinates, and  $(x2,y2)$  is the point of maximal coordinates.

```

⟨ Containment boxes 15a ⟩ ≡
    """ Containment boxes """
    def containmentBoxes(randomPointArray,qualifier=0):
        if len(randomPointArray[0])==2:
            boxes = [eval(vcode([min(x1,x2), min(y1,y2), min(z1,z2),
                                max(x1,x2), max(y1,y2), max(z1,z2)])))+[qualifier]
                    for ((x1,y1,z1),(x2,y2,z2)) in randomPointArray]
        elif len(randomPointArray[0])==3:
            boxes = [eval(vcode([min(x1,x2,x3), min(y1,y2,y3), min(z1,z2,z3),

```

```

        max(x1,x2,x3), max(y1,y2,y3), max(z1,z2,z3)))+[qualifier]
        for ((x1,y1,z1),(x2,y2,z2),(x3,y3,z3)) in randomPointArray]
elif len(randomPointArray[0])==4:
    boxes = [eval(vcode([min(x1,x2,x3,x4), min(y1,y2,y3,y4), min(z1,z2,z3,z4),
        max(x1,x2,x3,x4), max(y1,y2,y3,y4), max(z1,z2,z3,z4)))+[qualifier]
        for ((x1,y1,z1),(x2,y2,z2),(x3,y3,z3),(x4,y4,z4)) in randomPointArray]
    return boxes
◇

```

Macro referenced in 13a.

**Transformation of a 3D box into an hexahedron** The transformation of a 2D box into a closed rectangular polyline, given as an ordered sequwncw of 2D points, is produced by the function `box2exa`

```

⟨ Transformation of a 3D box into an hexahedron 15b ⟩ ≡
    """ Transformation of a 3D box into an hexahedron """
    def box2exa(box):
        x1,y1,z1,x2,y2,z2,type = box
        verts = [[x1,y1,z1], [x1,y1,z2], [x1,y2,z1], [x1,y2,z2], [x2,y1,z1], [x2,y1,z2], [x2,y2,z1], [x2,y2,z2]]
        cell = [range(1,len(verts)+1)]
        return [verts,cell,None],type

    def lar2boxes(model,qualifier=0):
        V,CV = model
        boxes = []
        for k,cell in enumerate(CV):
            verts = [V[v] for v in cell]
            x1,y1,z1 = [min(coord) for coord in TRANS(verts)]
            x2,y2,z2 = [max(coord) for coord in TRANS(verts)]
            boxes += [eval(vcode([min(x1,x2),min(y1,y2),min(z1,z2),max(x1,x2),max(y1,y2),max(z1,z2)])+[qualifier])
            return boxes
◇

```

Macro referenced in 13a.

**Computation of the 1D centroid of a list of 3D boxes** The 1D centroid of a list of 3D boxes is computed by the function given below. The direction of computation (either  $x$ ,  $y$  or  $z$ ) is chosen depending on the value of the `coord` parameter.

```

⟨ Computation of the 1D centroid of a list of 3D boxes 16 ⟩ ≡
    """ Computation of the 1D centroid of a list of 3D boxes """
    def centroid(boxes,coord):
        delta,n = 0,len(boxes)
        ncoords = len(boxes[0])/2
        a = coord%ncoords
        b = a+ncoords

```

```
    for box in boxes:
        delta += (box[a] + box[b])/2
    return delta/n
```
