

Accelerated intersection of geometric objects *

Alberto Paoluzzi

December 15, 2015

Abstract

This module contains the first experiments of a parallel implementation of the intersection of (multidimensional) geometric objects. The first installment is being oriented to the intersection of line segment in the 2D plane. A generalization of the algorithm, based on the classification of the containment boxes of the geometric values, will follow quickly.

1 Introduction

An easily parallelizable implementation of the accelerated intersection of geometric objects is given in this module. Our first aim is to implement a specialized version for simplices, that generalizes the nD -trees of points (that are 0-simplices), to $(d-1)$ -dimensional simplices in d -space, starting with the intersection of line segments in the plane. Our plan is to follow with an implementation for intersection of general *non convex* sets.

2 Implementation

The first implementation of this module concerns the computation of the intersection points among a set of line segment in the 2D plane. The containment boxes of the input segments are iteratively classified against the 1-dimensional centroid of smaller and smaller buckets of data.

At the end of the classification, where the same geometric object may be inserted in several different buckets, a *brute-force* intersection is applied to each final subset. Finally, the duplicated intersection points are removed, and a 1-dimensional LAR data structure is generated, with 1-cells given by the split line segments.

A complete LAR of the plane partition generated by the arrangement of lines is then computed by: (a) generating the maximal 2-connected components of such 1-dimensional graph; and (b) by traversing in counter-clockwise order the generated subgraphs to report the 2-dimensional cells of the plane partition.

The splitting algorithm may be easily parallelized, since both during their generation and at the end of this one, the various buckets of data can be dispatched to different processors for independent computation, followed by elimination of duplicates. In particular, a standard *map-reduce* software infrastructure may be used for this parallelization purpose.

2.1 Construction of independent buckets

Containment boxes Given as input a list `randomLineArray` of pairs of 2D points, the function `containment2DBoxes` returns, in the same order, the list of *containment boxes* of the input lines. A *containment box* of a geometric object of dimension d is defined as the minimal d -cuboid, equioriented with the reference frame, that contains the object. For a 2D line it is given by the tuple $(x1, y1, x2, y2)$, where $(x1, y1)$ is the point of minimal coordinates, and $(x2, y2)$ is the point of maximal coordinates.

\langle Containment boxes 2a $\rangle \equiv$

```
""" Containment boxes """

2.3 Generation of LAR representation of split segments

The function `lines2lar` is used to generate a 1-dimensional LAR complex from an array of lines, i.e. of pairs of 2D points. For every *line* in `frags` is computed an *ordered* list *outline* of *symbolic* intersection points, including the first and last vertex of the line, and every interior point generated by the list `params[k]`.

Then, for every symbolic representation *key* of a point in *outline*, a dictionary vertex is either created or retrieved, and a corresponding edge is orderly created, using the index of the point. At the same time, the vertices created in this way are accumulated within the *V* array. Finally, each edge in *EV* is extended to contain a second vertex index using the subsequent edge.

The third stage finalizes the vertex set of the output LAR, by identifying the closest vertices, i.e. those at distance less or equal to the current resolution, set to $10*(-PRECISION)$, by searching via the `scipy.spatialKDTree` the pairs of vertices at less than this distance.

A fourth stage identifies the possibly duplicated edges. Some of these could appear, e.g., when importing a set of adjacent boxes from some drawing program, to generate an array of lines, to be mutually intersected and transformed into a LAR data structure.

Create the LAR of fragmented lines

⟨ Create the LAR of fragmented lines 6 ⟩ ≡

```

""" Create the LAR of fragmented lines """
from scipy import spatial

def lines2lar(lineArray):
    _,params,frags = lineIntersection(lineArray)
    vertDict = dict()
    index,defaultValue,V,EV = -1,-1,[],[]

    for k,(p1,p2) in enumerate(frags):
        outline = [vcode(p1)]
        if params[k] != []:
            for alpha in params[k]:

```

```

        if alpha != 0.0 and alpha != 1.0:
            p = list(array(p1)+alpha*(array(p2)-array(p1)))
            outline += [vcode(p)]
outline += [vcode(p2)]

edge = []
for key in outline:
    if vertDict.get(key,defaultValue) == defaultValue:
        index += 1
        vertDict[key] = index
        edge += [index]
        V += [eval(key)]
    else:
        edge += [vertDict[key]]
EV.extend([[edge[k],edge[k+1]] for k,v in enumerate(edge[:-1])])

model = (V,EV)
return larSimplify(model)

```

2.5 2D cells from biconnected components

It is very easy, using the LAR representation of topology, to compute the 2-cells of the plane partitions (see Figures 1b and 1c) induced by the biconnected components extracted from a graph (1-complex).

In particular, let us consider the CSR (Compressed Sparse Row) representation of the characteristic matrix M_1 , here usually denoted as **EV**, in order to remark that we represent the edges on the rows, and the vertices on the columns of the matrix. As such it is a binary matrix. So, we can readily reconstruct the topology of 2-cells by associating to each non-zero (sparse) matrix element **angle_EV**(h,k) the angle in radians that the edge e_h forms with the horizontal line, when it incides on the vertex v_k .

Of course, if $e_h = (v_{k_1}, v_{k_2})$, then it will be

$$\mathbf{angle_EV}(h, k_2) = \mathbf{angle_EV}(h, k_1) + \pi = -\mathbf{angle_EV}(h, k_1)$$

Therefore, the columns of **angle_EV**, i.e. the rows of **angle_VE** := **angle_EV**^t, after being sorted on their angles α , and associated with the angle differences $\Delta\alpha$, will provide a basis

Figure 1: Two random line arrangements, and the biconnected components extracted by their LAR 1-complexes.

of elementary 1 – *cochains* that evaluate to zero for each closed 1-cochain, i.e. for every cycle supported by the linear space of 1-chains on the given line arrangement.

Slope of edges

Circular ordering of edges around vertices

⟨Slope of edges 9⟩ ≡

```

""" Circular ordering of edges around vertices """
def edgeSlopeOrdering(model):
    V,EV = model
    VE,VE_angle = invertRelation(EV),[]
    for v,ve in enumerate(VE):
        ve_angle = []
        if ve != []:
            for edge in ve:
                v0,v1 = EV[edge]
                if v == v0:    x,y = list(array(V[v1]) - array(V[v0]))
                elif v == v1:  x,y = list(array(V[v0]) - array(V[v1]))
                angle = math.atan2(y,x)
                ve_angle += [180*angle/PI]
            pairs = sorted(zip(ve_angle,ve))
            #VE_angle += [TRANS(pairs)[1]]
            VE_angle += [[pair[1] for pair in pairs]]
    return VE_angle

```

Ordered incidence relationship vertices to edges As we have seen, the `VE_angle` list of lists reports, for every vertex in `V`, the list of incident edges, *counterclockwise ordered* around the vertex. Therefore the `ordered_csrVE` function, given below, returns the “compressed sparse row” matrix, row-indexed by vertices and column-indexed by edges, and such that in position (v, e) contains the index ℓ of the next edge (after e , say) in the counterclockwise ordering of edges around v .

⟨Ordered incidence relationship of vertices and edges 11a⟩ ≡

```

""" Ordered incidence relationship of vertices and edges """
def ordered_csrVE(VE_angle):
    triples = []
    for v,ve in enumerate(VE_angle):
        n = len(ve)
        for k,edge in enumerate(ve):
            triples += [[v, ve[k], ve[(k+1)%n]]]
    csrVE = triples2mat(triples,shape="csr")

```

```
    return csrVE
```

◇

Macro referenced in 20c.

Faces from biconnected components Since edges in the plane partition induced by a line arrangement are $(d-1)$ -cells, they are located on the boundary of *two* d -cells (faces) of the partition. Hence, the traversal algorithm of the data structure storing the relevant information may be driven by signing the two extremes (vertices) of each edge as either already visited or not.

```
< Faces from biconnected components 11b > ≡
    """ Faces from biconnected components """

    def firstSearch(visited):
        for edge,vertices in enumerate(visited):
            for v,vertex in enumerate(vertices):
                if visited[edge,v] == 0.0:
                    visited[edge,v] = 1.0
                    return edge,v
            return -1,-1

    def facesFromComps(model):
        V,EV = model
        # Remove zero edges
        EV = list(set([ tuple(sorted([v1,v2])) for v1,v2 in EV if v1!=v2 ]))
        FV = []
        VE_angle = edgeSlopeOrdering((V,EV))
        csrEV = ordered_csrVE(VE_angle).T
        visited = zeros((len(EV),2))
        edge,v = firstSearch(visited)
        vertex = EV[edge][v]
        fv = []
        while True:
            if (edge,v) == (-1,-1):
                break #return [face for face in FV if face != None]
            elif (fv == []) or (fv[0] != vertex):

                fv += [vertex]
                nextEdge = csrEV[edge,vertex]
                v0,v1 = EV[nextEdge]

                try:
                    vertex, = set([v0,v1]).difference([vertex])

Example The *ordered csrVE* (vertex-edge) matrix generated by the example of file `test/py/inters/test07.py` is shown in dense format in the example script below. Let us notice the each non-zero element $\text{csrVE}(k, h)$ stores the index of the previous edge inciding on the vertex v_k *before* the edge e_h . The traversal of the data structure is made accordingly, in order to extract the vertices of all the faces (minimal edge cycles) generated by a line arrangement in the plane.

⟨ Example of VE matrix with nextEdge indices 13a ⟩ ≡

```

2.6 Transformation of an array of lines in a 2D LAR complex

Transformation of an array of lines in a 2D LAR complex The whole transformation of an array of lines into a two-dimensional LAR complex is executed by the function `larFromLines`. The function returns the model triple `V,FV,EV`. The last element in `FV` is the *ordered* boundary chain. just notice that

⟨Transformation of an array of lines in a 2D LAR complex 13b⟩ ≡

```

""" Transformation of an array of lines in a 2D LAR complex """
def larFromLines(lines):
    V,EV = lines2lar(lines)
    #VIEW(EXPLODE(1.2,1.2,1.2)(MKPOLs((V,EV))))
    V,EVs = biconnectedComponent((V,EV))
    if EVs != []:
        EV = list(set(AA(tuple)(AA(sorted)(max(EVs, key=len)))))) ## NB
        V,EV = larRemoveVertices(V,EV)
        V,FV,EV = facesFromComps((V,EV))
        areas = integr.surfIntegration((V,FV,EV))
        orderedFaces = sorted([[area,FV[f]] for f,area in enumerate(areas)])
        interiorFaces = [face for area,face in orderedFaces[:-1]]
        return V,interiorFaces,EV
    else: return None

```

2.7 Pruning LAR models from parts out of proper resolution

Pruning of clusters of too close vertices is executed by taking a LAR model as input, executing the following computations, and producing a new simplified LAR model.

Pruning away clusters of close vertices First, reduce the array of vertices `pts` to its *quotient set* with respect to the transitive closure of the relation of “nearness”. Two vertices are “near” when their (Euclidean) distance is less than a given `RADIUS`. The subgraphs of the graph of this relation are *contracted* in a single point, set to the centroid of the vertices of the subgraph. The function `W` takes as input the array `pts` of vertex points, and returns: (a) the array `newV` of new vertices; (b) the list of lists `close` of sorted indices of pairs of close vertices, removed from duplicates; (c) the list of `clusters` of `pts` indices; (d) the integer `vmap` array, mapping old vertex indices to new vertex indices.

⟨Pruning away clusters of close vertices 14⟩ ≡

```

""" Pruning away clusters of close vertices """
from scipy.spatial import cKDTree

```

```

def pruneVertices(pts,radius=0.001):
    tree = cKDTree(pts)
    a = cKDTree.sparse_distance_matrix(tree,tree,radius)
    print a.keys()
    close = list(set(AA(tuple)(AA(sorted)(a.keys()))))
    import networkx as nx
    G=nx.Graph()
    G.add_nodes_from(range(len(pts)))
    G.add_edges_from(close)
    clusters, k, h = [], 0, 0

    subgraphs = list(nx.connected_component_subgraphs(G))
    V = [None for subgraph in subgraphs]
    vmap = [None for k in xrange(len(pts))]
    for k,subgraph in enumerate(subgraphs):
        group = subgraph.nodes()
        if len(group)>1:
            V[k] = CCOMB([pts[v] for v in group])
            for v in group: vmap[v] = k
            clusters += [group]
        else:
            oldNode = group[0]
            V[k] = pts[oldNode]
            vmap[oldNode] = k
    return V,close,clusters,vmap

```

◇

Macro referenced in [20c](#).

Export a simplified LAR model Next, update the arrays of compressed characteristic matrices of a Linear Algebraic Representation. The standard approach is to read row-wise the arrays of matrices of incidence of cells on vertices; translate every index using the `vmap` array, mapping old vertex indices to new ones; remove repeated indices and substitute them with a single instance; check if the new index list has length greater or equal to the number of vertices of the simplex of the proper dimension. Finally, write an output cell if and only if the previous test is true.

```

⟨Return a simplified LAR model 15⟩ ≡
""" Return a simplified LAR model """
def larSimplify(model,radius=0.001):
    if len(model)==2: V,CV = model
    elif len(model)==3: V,CV,FV = model
    else: print "ERROR: model input"

    W,close,clusters,vmap = pruneVertices(V,radius)
    celldim = DIM(MKPOL([V,[[v+1 for v in CV[0]],None]]))

```

```

newCV = [list(set([vmap[v] for v in cell])) for cell in CV]
CV = list(set([tuple(sorted(cell)) for cell in newCV if len(cell) >= celldim+1]))
CV = sorted(CV,key=len) # to get the boundary cell as last one (in most cases)

if len(model)==3:
    celldim = DIM(MKPOL([V,[v+1 for v in FV[0]]],None)))
    newFV = [list(set([vmap[v] for v in facet])) for facet in FV]
    FV = [facet for facet in newFV if len(facet) >= celldim]
    FV = list(set(AA(tuple)(AA(sorted)(FV))))
    return W,CV,FV
else: return W,CV

2.8 Drawing multiply-connected boundary polylines

A multiply-connected boundary polyline gives the boundary edges of a 2-cell. In LAR, 2-cells must be connected, but not necessarily simply-connected (or path-connected, or homotopic to a point). The “solid” drawing of such a generally non-convex 2-cells is not easy. In particular, they must be decomposed into a coherently-oriented simplicial 2-complex, i.e. into a set of equioriented triangles. The library function used at this purpose `()`, contained in the `poly2tria` module, only accepts a single boundary polyline. Hence the purpose of this section is to transform a list of cycles, corresponding orderly to the exterior and the interior boundaries of a 2-cell, into a single polyline, using the so-called *bridge-edges* [YT85] mechanism. The transformation from a set of non-intersecting boundary cycles to a single connected polyline is given in Section ??.

Generating the LAR of a set of non-intersecting cycle We use the `test/svg/lattice.svg` file to test the exporting of different boundary chains. The example `test15.py` aims to prepare the computational environment for writing down the LAR of the 2-complex generated by any set of non-intersecting 1-cles in 2D.

Let us remember that any d -cell in the domain of the LAR scheme must be connected, but not necessarily contractible to a point, i.e. may contain internal holes. The goal of this test and of the previous one, is hence to generalize the creation of 2-complexes (sets of polygons) starting from several non-intersecting boundary cycles, instead than starting from just one closed polyline.

The motivation arises from situations created by the Boolean algorithm, as well as from the input of a 2-complex from general wire-frame drawings.

```

"test/py/inters/test16.py" 17 ≡
    """ Generating the LAR of a set of non-intersecting cycles """
    from larlib import *

    sys.path.insert(0, 'test/py/inters/')
    from test15 import *

    cells = cellsFromCycles(testArray)
    CV = AA(COMP([list,set,CAT]))(EVs)
    EVdict = dict(zip(EV,range(len(EV))))
    FE = [[EVdict[edge] for edge in cycle] for cycle in EVs]
    edges = [CAT([FE[cycle] for cycle in cell]) for cell in cells]
    FVs = [[CV[cycle] for cycle in cell] for cell in cells]
    FV = AA(CAT)(FVs)

    n = len(cells)
    chains = allBinarySubsetsOfLenght(n)

    cycles = STRUCT(MKPOLS((V,EV)))
    csrBoundaryMat = boundary(FV,EV)
    for chain in chains:
        chainBoundary = COLOR(RED)(STRUCT(MKPOLS((V,[EV[e]
                                                    for e in chain2BoundaryChain(csrBoundaryMat)(chain)]))))
        VIEW(STRUCT([cycles, chainBoundary]))
    ◇

```

LAR of the 2-complex generated by non-intersecting cycles Therefore, the LAR of the 2-complex generated from the input get from test15.py is (V,FV,EV) with the components given by the the following:

```

V = [[0.7808,0.6751],[0.6044,0.6751],[0.319,0.5804],[0.319,0.3994],[0.8936,0.0],
      [0.0,0.0],[0.6044,0.8123],[0.7808,0.8123],[0.3495,0.6751],[0.3495,0.8123],
      [0.1218,0.3036],[0.2983,0.3036],[0.0886,0.3994],[0.0886,0.5804],[0.2581,0.4505],
      [0.1495,0.4505],[0.7717,0.4213],[0.5952,0.4213],[0.7717,0.5585],[0.0,1.0],
      [0.3403,0.1664],[0.3403,0.3036],[0.5952,0.5585],[0.5168,0.1664],[0.5168,0.3036],
      [0.5259,0.8123],[0.1495,0.5293],[0.5259,0.6751],[0.8936,1.0],[0.2983,0.1664],
      [0.1218,0.1664],[0.2581,0.5293],[0.4965,0.7815],[0.4965,0.7059],[0.2983,
      0.5585],[0.2983,0.4213],[0.1218,0.4213],[0.3789,0.7815],[0.1218,0.5585],
      [0.3789,0.7059]]

```

```

FV = [[0,1,2,3,4,5,6,7,8,9,10,11,12,13,16,17,18,19,20,21,22,23,24,25,27,
      28,29,30],[32,33,37,39],[34,35,36,38,26,15,14,31]]

```

```

EV = [(0,1),(0,7),(1,6),(2,3),(2,13),(3,12),(4,5),(4,28),(5,19),(6,7),(8,9),

```

(8,27),(9,25),(10,11),(10,30),(11,29),(12,13),(14,15),(14,31),(15,26),
(16,17),(16,18),(17,22),(18,22),(19,28),(20,21),(20,23),(21,24),(23,24),
(25,27),(26,31),(29,30),(32,33),(32,37),(33,39),(34,35),(34,38),(35,36),
(36,38),(37,39)]

Of course, this LAR representation gives full control of the complex topology, including k -(co)chains and (co)boundary operators. For example, in Figure 2 we show a solid image of the three 2-cells in FV, and, drawn in red the boundary 1-cells in the complex, corresponding to the 2-chains of coordinates $[1, 0, 0]$, $[0, 1, 0]$, $[0, 0, 1]$, and $[1, 1, 0]$, respectively.

Figure 2: Some examples of boundaries (in red) of 2-chains from nested non intersecting cycles.

2.9 Boundary polylines

Generating the LAR of a set of non-intersecting cycles The example provided by `test/py/inters/test17.py` is completed here by showing the solid drawing of the generated LAR data structure, and superimposing to it the boundary 1-chains generated by several 2-chains.

SVG input parsing and transformation We postulate here that the input file `test/py/inters/test.svg` should contain only `<line>` primitives, so we skip any other content. Such primitives are parsed by matching against regular expressions, and their `x1,y1,x2,y2` attributes are extracted and stored into the `lines` variable. An isomorphic window-viewport transformation is then performed, to transform the data within the standard unit 2D square $[0,1]^2$. The input vertices are finally set to a fixed resolution, using the `vcode` function.

$\langle \text{SVG input parsing and transformation 28} \rangle \equiv$

Figure 7: LAR complex generation from SVG file. (a) the input set of lines; (b) imported in pyplasm environment; (c) the extracted *regularized* 2-complex, drawn exploded.

◇

```

Macro referenced in 28.

2-complex extraction from svg file The input `lines` arrangements produces a 1-dimensional complex stored into the LAR model V, EV . Then the *dangling edges* are removed from EV , and the whole data set is renumbered, in order to remove the unused vertices, using the `larRemoveVertices` function. Finally the 2-cells are computed and stored in FV , and the positive areas of every 2cells are computed, so allowing for identify and removal of

the exterior face, corresponding to the boundary of the complex. The polygonal boundary of the complex is finally drawn.

A Code utilities

Coding utilities Some utility fuctions used by the module are collected in this appendix. Their macro names can be seen in the below script.

```

⟨ Coding utilities 32b ⟩ ≡
    """ Coding utilities """
    ⟨ Generation of all binary subsets of lenght n 32c ⟩
    ⟨ Generation of a random point 33b ⟩
    ⟨ Generation of a random line segment 33c ⟩
    ⟨ Transformation of a 2D box into a closed polyline 34a ⟩
    ⟨ Computation of the 1D centroid of a list of 2D boxes 34b ⟩
    ⟨ Pyplasm XOR of FAN of ordered points 35 ⟩
    ◇

```

Macro referenced in 20c.

Generation of all binary subsets of lenght n

```

⟨ Generation of all binary subsets of lenght n 32c ⟩ ≡
    """ Generation of all binary subsets of lenght n """
    def allBinarySubsetsOfLenght(n):
        out = [list(('0:0'+str(n)+'b').format(k)) for k in range(1,2**n)]
        return AA(AA(int))(out)
    ◇

```

Macro referenced in 32b.

Example

```

In [9]: allBinarySubsetsOfLenght(3)
Out[9]: [[0,0,1],[0,1,0],[0,1,1],[1,0,0],[1,0,1],[1,1,0],[1,1,1]]

```

Generation of random lines The function `randomLines` returns the array `randomLineArray` with a given number of lines generated within the unit 2D interval. The `scaling` parameter is used to scale every such line, generated by two randow points, that could be possibly located to far from each other, even at the distance of the diagonal of the unit square.

The arrays `xs` and `ys`, that contain the x and y coordinates of line points, are used to compute the minimal translation v needed to transport the entire set of data within the positive quadrant of the 2D plane.

```

⟨ Generation of random lines 33a ⟩ ≡

```

```

""" Generation of random lines """
def randomLines(numberOfLines=200,scaling=0.3):
    randomLineArray = [redge(scaling) for k in range(numberOfLines)]
    [xs,ys] = TRANS(CAT(randomLineArray))[:2]
    xmin, ymin = min(xs), min(ys)
    v = array([-xmin,-ymin])
    randomLineArray = [[list(v1[:2]+v), list(v2[:2]+v)] for v1,v2 in randomLineArray]
    return randomLineArray

```

◇

Macro referenced in 20c.

Generation of a random point A single random point, codified in floating point format, and with a fixed (quite small) number of digits, is returned by the `rpoint2d()` function, with no input parameters.

⟨ Generation of a random point 33b ⟩ ≡

```

""" Generation of a random point """
def rpoint2d():
    return eval( vcode([ random.random(), random.random() ]) )

```

◇

Macro referenced in 32b.

Generation of a random line segment A single random segment, scaled about its centroid by the `scaling` parameter, is returned by the `redge()` function, as a tuple of two random points in the unit square.

⟨ Generation of a random line segment 33c ⟩ ≡

```

""" Generation of a random line segment """
def redge(scaling):
    v1,v2 = array(rpoint2d()), array(rpoint2d())
    c = (v1+v2)/2
    pos = rpoint2d()
    v1 = (v1-c)*scaling + pos
    v2 = (v2-c)*scaling + pos
    return tuple(eval(vcode(v1))), tuple(eval(vcode(v2)))

```

◇

Macro referenced in 32b.

Transformation of a 2D box into a closed polyline The transformation of a 2D box into a closed rectangular polyline, given as an ordered sequwncw of 2D points, is produced by the function `box2rect`

⟨ Transformation of a 2D box into a closed polyline 34a ⟩ ≡

```

""" Transformation of a 2D box into a closed polyline """
def box2rect(box):
    x1,y1,x2,y2 = box
    verts = [[x1,y1],[x2,y1],[x2,y2],[x1,y2],[x1,y1]]
    return verts

```

Macro referenced in 32b.

Computation of the 1D centroid of a list of 2D boxes The 1D centroid of a list of 2D boxes is computed by the function given below. The direction of computation (either x or y) is chosen depending on the value of the `xy` parameter.

⟨ Computation of the 1D centroid of a list of 2D boxes 34b ⟩ ≡

```

""" Computation of the 1D centroid of a list of 2D boxes """
def centroid(boxes,coord):
    delta,n = 0,len(boxes)
    ncoords = len(boxes[0])/2
    a = coord%ncoords
    b = a+ncoords
    for box in boxes:
        delta += (box[a] + box[b])/2
    return delta/n

```

Macro referenced in 32b.
