

Structured input to HIJSON

Towards indoor mapping and IoT modeling *

Alberto Paoluzzi

October 17, 2015

Abstract

This module aims to prototype the process of entering geometric data representing a complex building, to provide them explicit semantic and a hierarchical model. The generated LAR structures [DPS14, PDFJ15] are finally output to HIJSON format, an experimental data format extending GEOJSON for applications of indoor mapping and the Internet-of-Things. In HIJSON a strongly simplified building model, yet sufficient for useful purposes, accomodates the knowledge concerning the use models of the building and the set of interior devices and their connection.

1 Introduction

2 Implementation

2.1 Input of geometry from external drawings

File input and computation of cellular complex The modeling process starts with the input of a `.svg` file, the W3C standard for 2D vector graphics on the web. The file must only contain (by now) `<rect>` and `<line>` graphics primitives. The geometric data generate the partition of the plane induced by an arrangement of intersecting lines. The arrangement of (fragmented) lines is finally transformed into a 2D *LAR model*, made by the triple V, FV, EV of vertices, faces and edges. We notice the the LAR input is normalized by the `larFromLines` function: all vertices in V are transformed in the standard plane interval $[0, 1]^2$.

```
<SVG file input and computation of cellular complex 2a>  $\equiv$ 
    """ File input and computation of cellular complex """
    def svg2lar(filename):
        lines = svg2lines(filename)
        larModel = larFromLines(lines)
        V, FV, EV = larModel
        return larModel
     $\diamond$ 
```

Macro referenced in [5a](#).

2.2 Emulation of interactive graphics input

In this section two functions are given to emulate two graphics input primitives, respectively.

Emulation of input from “selection box” The function accepts as input the LAR model V, FV, EV and a `queryBox` given in normalized coordinates. It returns `vertexSubset` $\subseteq V$, `faceSubset` $\subseteq FV$, `edgeSubset` $\subseteq EV$.

```
<Emulation of input from “selection box” 2b>  $\equiv$ 

    """ Emulation of input from “selection box” over a LAR normalized representation """
    from scipy import spatial

    def subComplexInBox(V, FV, EV, queryBox):
        (xmin, ymin), (xmax, ymax) = queryBox
        if xmin > xmax: xmin, xmax = xmax, xmin
        if ymin > ymax: ymin, ymax = ymax, ymin
        vdict = dict([(vcode(vert), k) for k, vert in enumerate(V)])
```

```

vertexSubset = [vdict[vcode((x,y))] for x,y in V if xmin<=x<=xmax and ymin<=y<=ymax]
edgeSubset = [e for e,edge in enumerate(EV) if all([v in vertexSubset for v in edge])]
faceSubset = [f for f,face in enumerate(FV) if all([v in vertexSubset for v in face])]
return vertexSubset,faceSubset,edgeSubset

if __name__=="__main__":
    selectBox = ((0.45, 0.45), (0.65, 0.75))
    vertexSubset,faceSubset,edgeSubset = subComplexInBox(V,FV,EV,selectBox)
    #VIEW(EXPLODE(1.2,1.2,1.2)(MKPOLLS((V,[EV[e] for e in edgeSubset])) + [
        #COLOR(RED)(MK(selectBox[0])), COLOR(RED)(MK(selectBox[1]))]))
    #VIEW(EXPLODE(1.2,1.2,1.2)(MKPOLLS((V,[FV[f] for f in faceSubset])) + [
        #COLOR(RED)(MK(selectBox[0])), COLOR(RED)(MK(selectBox[1]))]))

```

◇

Macro referenced in 5a.

Emulation of “pick” input over a LAR normalized representation The function accepts as input the LAR model V, FV, EV , the incidence relation FE , that provides for each face the list of incident edges, and a `queryPoint` given in normalized coordinates. It returns $vertexSubset \subseteq V$, $faceSubset \subseteq FV$, $edgeSubset \subseteq EV$.

⟨ Emulation of “pick” input 3a ⟩ ≡

```

""" Emulation of ‘pick’ input over a LAR normalized representation """
def subComplexAroundPoint(V,FV,EV,FE,queryPoint):
    tree = spatial.cKDTree(V)
    pts = np.array([queryPoint])
    dist,closestVertex = tree.query(pts)
    VF = invertRelation(FV)
    closestFaces = VF[closestVertex]
    for face in closestFaces:
        faceEdges = [EV[e] for e in FE[face]]
        if pointInPolygonClassification(queryPoint, (V,faceEdges)) == "p_in":
            break
    vertexSubset = FV[face]
    edgeSubset = [EV[e] for e in FE[face]]
    faceSubset = [face]
    return vertexSubset,faceSubset,edgeSubset

if __name__=="__main__":
    FE = crossRelation(FV,EV)
    queryPoint = (0.6,0.58)
    vertexSubset,faceSubset,edgeSubset = subComplexAroundPoint(V,FV,EV,FE,queryPoint)
    ##VIEW(EXPLODE(1.2,1.2,1.2)(MKPOLLS((V,[EV[e] for e in FE[faceSubset[0]]])) + [
        #COLOR(RED)(MK(queryPoint))]) )

```

◇

Macro referenced in 5a.

From LAR chain to colored HPCs The function `cells2hpcs` is used to assign a given `k` color to the cells of a chain (cell subset) of a LAR model `V,FV`. The function returns a list of HPC (colored) objects.

```

⟨From LAR chain to colored HPCs 3b⟩ ≡
    """ From LAR chain to colored HPCs """
    def cells2hpcs(V,FV,cells,k):
        colors = [RED, GREEN, BLUE, CYAN, MAGENTA, YELLOW, WHITE, PURPLE, BROWN]
        return AA(COLOR(colors[k]))(MKPOLs((V,[FV[f] for f in cells])))
    ◇

```

Macro referenced in [5a](#).

2.3 Structural operations

From 2D chains to boundary chains

```

⟨From 2D chains to boundary chains 4a⟩ ≡
    """ From 2D chains to boundary chains """
    def chain2BoundaryChain(FV,EV):
        csrBoundaryMat = boundary(FV,EV)
        nedges,nfaces = csrBoundaryMat.shape
        def chain2BoundaryChain0(chain):
            row = np.array(chain)
            col = np.array([0 for k in range(len(chain))])
            data = np.array([1 for k in range(len(chain))])
            csrFaceVect = scipy.sparse.coo_matrix((data, (row, col)), shape=(nfaces,1)).tocsr()
            csrEdgeVect = csrBoundaryMat*csrFaceVect
            boundaryChain = [h for h,val in
                zip(csrEdgeVect.tocoo().row, csrEdgeVect.tocoo().data) if val%2 != 0]
            return boundaryChain
        return chain2BoundaryChain0
    ◇

```

Macro referenced in [5a](#).

From chains to structures

```

⟨From chains to structures 4b⟩ ≡
    """ From chains to structures """
    def chain2structs(V,FV,EV,FE):
        def chain2structs0(args):
            if args == ([],[],[]): return
            chain,chainName,classtype = args
            struct = []
            for cell in chain:
                vs = [V[v] for v in FV[cell]]

```

```

        vdict = dict([[vcode(vert),k] for k,vert in enumerate(vs)])
        facetEdges = [[V[v] for v in EV[e]] for e in FE[cell]]
        ev = [(vdict[vcode(v1)], vdict[vcode(v2)]) for v1,v2 in facetEdges]
        fv = [range(len(vs))]
        shape = vs,fv,ev
        struct += [ Struct([ shape ], name=None, category="room" ) ]
        out = Struct( struct, name=chainName, category=classtype )
        return out
    return chain2structs0

```

◇

Macro referenced in 5a.

3 Exporting the library

```

"larlib/larlib/hijson.py" 5a ≡
    """ Module for Structured input to HIJSON """
    from larlib import *
    from copy import copy
    DEBUG = False
